**ABSTRACT:** The Standard Penetrating Test (SPT) can be considered as one of the most common in-situ popular and economic tests for subsurface investigation. Therefore, many empirical correlations have been developed between the SPT N-value, and other properties of soil. The principle objective of the current study is to demonstrate the feasibility and efficiency of using artificial neural networks (ANNs) to predict the soil angle of internal friction ( $\Phi$ ), the soil modulus of elasticity (E) and tip resistance ( $q_c$ ) of cone penetration test (CPT) results from SPT results considering the uncertainty and non-linearity of the soil. In addition, ANNs are used to study the influence of different input parameters that can be used to improve the prediction. A large amount of field and experimental data including SPT/CPT results, plate load tests, direct shear box, grain size distribution was obtained from a project in the United Arab Emirates to be used in the training and the validation of the ANNs. The ANN results are compared with some common traditional correlations. The results show that the developed ANNs can efficiently predict the aimed parameters from the SPT results. The predicted parameters from ANN are in very good agreement with the measured results compared to the predicted values from available traditional correlations.

*Keywords: Angle of Internal Friction; Cone Penetrating Test; General Regression Neural Network; Soil Modulus of Elasticity, Standard Penetrating Test.*

### 1. INTRODUCTION

The Standard Penetration Test (SPT) is one of the most commonly used in-situ tests for site investigation and foundation design. Many empirical correlations have been developed between the SPT N-value, and other engineering properties of soil. Despite the fact that this test has disadvantages such as discrete strength measurement and dependence on operator and apparatus, it is still the most popular and economic mean for subsurface investigation.

The current paper studies the feasibility and efficiency of using artificial neural networks (ANNs) to estimate the soil properties  $\Phi$  (angle of internal friction), E (modulus of elasticity) and  $q_c$  (tip resistance of cone penetration test (CPT)) [1]-[5] from SPT results. In addition, the study investigates which parameters should be included in the soil property estimation to improve the prediction models.

Artificial neural networks have been intensively studied and applied to many geotechnical engineering problems. In addition, It has been applied to estimate many soil and material properties and it is proved to be a powerful tool that can have superiority over other correlation techniques [6] - [10]. The idea of neural network technology is similar to the brain's own problem-solving process. An ANN is composed of a large

number of connected neurons which act like simple processors. Generally, when a large volume of data is available for training, ANNs offer viable solutions. It has been shown that ANNs are capable of mapping nonlinear and complex relationships in nature and are very beneficial when a problem is difficult to formulate analytically.

To train and test a neural network a large amount of data is needed. In the current study, field and experimental data including SPT/ CPT results, plate load tests, direct shear box, grain size distribution were obtained then filtered and processed from a large-scale project that covers the United Arab Emirates (UAE). The soil in UAE is mostly cohesionless soil. UAE is witnessing a lot of development and many construction projects. It is believed that using data from such active areas in construction for prediction of soil properties would be of benefit to engineers in this area specifically and to geotechnical engineers in general.

The available data used for estimating  $\Phi$  (Direct shear box), E (plate loading test) and  $q_c$  (CPT results) from N (SPT results), is first presented. The different ANN models are then developed. Different input parameters were considered to study the influence of the input parameters on the ANN models. The predictions from ANN are compared to predictions from other correlations available in the literature. Conclusions highlighting the efficiency of the ANNs are finally presented.

## 2. AVAILABLE DATA

The data for this study was collected from the results of geotechnical investigation work that had been done for a large-scale project. The project extends all over United Arab Emirates (UAE) where the soil is mainly cohesionless soil.

The project had about 820 boreholes with variable depths including standard penetration tests (SPT) for each borehole along the project alignment. Additionally, 400 cone penetration tests (CPT) were executed beside the boreholes. Moreover, there were 630 test-pits with maximum depth of 3.0m with 260 plate loading tests to determine the modulus of soil elasticity and 606 California Bearing Ratio tests (CBR). Lab tests were performed on the soil samples for classification (grain size distribution tests; sieve analysis and hydrometer) and for determining the shear strength parameters (direct shear box).

## 3. NEURAL NETWORK MODELING

The current study uses a supervised ANN. In a supervised network, a large number of correct predictions are given to the model from which it can learn. Examples of supervised networks are back propagation networks (BPN), general regression neural networks (GRNN) and probabilistic neural networks (PNN) [11], [12].

The architecture of a supervised ANN, generally, consists of an input layer, an output layer and one or more hidden layers. The input layer contains the input variables. The output layer contains the target output vector. At least one hidden layer that contains the artificial neurons (processing units) is used between the input and output to assist in the learning process. The neurons in the different layers are interconnected. Each connection has a 'weight' associated with it. Input values in the first layer are weighted and passed on to the hidden layer. Neurons in the hidden layer produce outputs by applying an activation function to the sum of the weighted input values [11], [12]. These outputs are then weighted by the connections between the hidden and output layer. The output layer produces the desired results.

Two main phases are included in neural network operation. The first is the training phase and the second is the testing phase. In the first phase the data is repeatedly presented to the network while the weights of the data are updated to obtain the desired output. In the second phase the trained network with the frozen weights is applied to data it has never seen. A properly trained network can model the unknown function that relates the input variables to the output variables. It can then be used to make

predictions for a given set of previously unseen input patterns where the output values are unknown.

The neural networks used in the current study were developed using the neural network program Neuroshell 2 [13]. This program implements several different neural network algorithms. The general regression neural network (GRNN) was used in the current study. GRNNs are known for their ability to train quickly on sparse data sets [10].

The GRNN models developed were three-layer networks (input layer, output layer and one hidden layer). The number of neurons in the input layer is equal to the number of inputs while the number of neurons in the output layer is equal to the number of outputs. The number of neurons in the hidden layer is usually equal to the number of correct patterns given to the model to learn from.

The inputs were scaled using a linear scale function [0,1]. The GRNN used was genetic adaptive; i.e. it uses a genetic algorithm to find an input smoothing factor adjustment. The genetic breeding pool size of 100 was used in the developed GRNN. An initial smoothing factor was taken as 0.3. The smoothing factor is an important parameter in the GRNN which determines how tightly the network matches its predictions to the data in the training patterns.

For each of the data sets prepared to estimate  $\Phi$ ,  $E$  and  $q_c$  from  $N$ , 20% of the data was randomly extracted. This 20% was used as a testing set while the rest of the data was used as a training set.

## 4. ESTIMATING $\Phi$ FROM SPT RESULTS

### 4.1 Output/Input Variables of ANN Analysis

For estimating  $\Phi$  from SPT results, the SPT results ( $N$  values), direct shear test and grain size analysis were used from the available data. The readings of the SPT test were filtered to be at the same elevation of the lab tests. A total of 84 data points were prepared. The parameters that were investigated as input parameters to be included in the GRNN models developed were  $N$  (obtained from SPT results),  $F_c$  (fines content),  $D_{50}$  (defined as grain diameter corresponding to 50% of the material being smaller) obtained from grain size analysis and  $\sigma_{\text{eff}}$  (the effective overburden pressure) calculated at the same level of the SPT test. The calculation of effective overburden pressure was based on a unit weight of soil of  $18 \text{ KN/m}^3$  and the unit weight of water of  $10 \text{ KN/m}^3$  taking into consideration the effect of ground water level.

The output of the GRNN models considered was  $\tan \Phi$  which was both measured (obtained from direct shear box) and estimated by the GRNN models developed. Five different GRNN models

were developed with different input parameters to study the influence of the input parameters on the obtained  $\tan \Phi$ . To evaluate the efficiency of the GRNN models developed, the coefficient of correlation ( $r^2$ ) was used.  $r^2$  is a statistical measure of the strength of the relationship between the actual versus predicted outputs.  $r^2$  value of 1 indicates a perfect fit, while that of 0 indicates no relationship.

**4.2 Results of Neural Networks**

Fig. 1 shows 5 different GRNN models developed (GRNN1 to GRNN5) with 5 different input combinations and the corresponding  $r^2$  (for all data points) obtained for each Network. GRNN2 with inputs (N,  $\sigma_{eff}$ ) was the best model to represent the correlation of predicting ( $\tan\Phi$ ) from SPT results and effective overburden with a high value of  $r^2$  of 97.55%.

Table 1 presents the data used in GRNN2 as input and the measured  $\tan \Phi$ . The comparison between the predicted  $\tan \Phi$  from GRNN and the actual measured values is presented in Fig. 2.

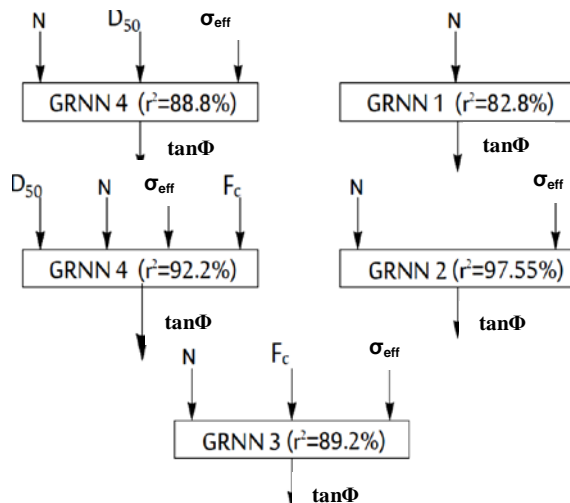

Fig. 1 Trials used to predict  $\tan (\Phi)$  from SPT results considering different input parameters with  $r^2$  coefficient (%)

For GRNN2, the weight (influence) of each input parameter on the relation is reflected by the individual smoothing factor of each input parameter. The individual smoothing factors for each input are shown in Fig. 2. It is concluded from Fig. 2 that ( $\sigma_{eff}$ ) is the second input variable that influences the network and N- value (SPT result) is the first one.

Fig.2 The weight factors for the correlation between angle of internal friction and SPT results (GRNN2)

### 4.3 Comparison between Neural Networks and a Set of Traditional Methods

Table 2 shows some of the correlations used for the estimation of  $\Phi$  from SPT results available in the literature. The available data is applied to the available correlations in the literature and are plotted in Fig. 3 along with the results from the ANN model developed.

From Fig. 3, it is clear that the ANN model predicted values of angle of internal friction are very close to the measured values compared to the other available correlations. Therefore, it is a good indication for the applicability of using this model in comparison with other correlations

## 5. ESTIMATING E FROM SPT RESULTS

### 5.1 Output/Input Variables of ANN Analysis

For estimating E from SPT results, the SPT results (N values), plate loading test and grain size analysis were used from the available data. The readings of the SPT test were filtered to be at the same elevation of the lab tests and at the zone of 120 cm below plate loading test (influence zone while the plate width is 60cm). Thirty-four data points were prepared. The parameters that were investigated as input parameters to be included in the GRNN models developed were N (obtained from SPT results),  $F_c$  (fines content),  $D_{50}$  and depth of water below the plate loading test.

### 5.2 Results of Neural Networks

Fig. 4 shows 7 different GRNN models developed (GRNN1 to GRNN7) with 7 different input combinations and the corresponding  $r^2$  (for all data points) obtained for each Network. GRNN2 with inputs (N,  $D_{50}$ ) was the best model to represent the correlation of predicting (E) from SPT results with a high value of  $r^2$  of 95.46%. Fig. 5 shows the influence/weight factors for every input.

Table 3 presents the data used as input and the measured E. Fig. 6 shows the comparison between the predicted E from GRNN2 and the actual measured values.

## 6. ESTIMATING (q<sub>c</sub>) FROM SPT RESULTS

### 6.1 Output/Input Variables of ANN Analysis

For estimating q<sub>c</sub> from SPT results, the SPT results (N values), results of grain size analysis (F<sub>c</sub>, D<sub>50</sub>, D<sub>30</sub>, D<sub>10</sub>) and effective overburden pressure (σ<sub>eff</sub>) were used from the available data. The readings of the CPT tests were filtered to be at the same elevation of the lab tests and N-value of SPT. A total of 93 data points were prepared.

### 6.2 Results of Neural Networks

Fig. 8 shows 10 different GRNN models developed (GRNN1 to GRNN10) with 10 different input combinations and the corresponding r<sup>2</sup> (for all data points) obtained for each Network. GRNN7 with inputs (N, F<sub>c</sub>, D<sub>50</sub>, D<sub>30</sub>, D<sub>10</sub>, σ<sub>eff</sub>) was the best model to represent the correlation of predicting (q<sub>c</sub>) from SPT results, effective overburden and results of grain size distribution tests with a high value of r<sup>2</sup> of 90%.

Fig. 9 shows the influence factors for every input for GRNN3, GRNN4, GRNN7, GRNN8 that have r<sup>2</sup> > 90%, however, GRNN7 is considered the strong correlation between q<sub>c</sub> (CPT result) and N-value of SPT result because N-value has a high influence factor of 2.77 and is considered the last factor in the

other correlations (GRNN3, GRNN4, GRNN8). In addition,  $D_{50}$  is the last factor that has no effect on output results for GRNN7.

Table 5 presents the data used in GRNN7 as input and the measured  $q_c$ . Fig. 10 shows the comparison between the predicted  $q_c$  from GRNN7 and the actual measured values.

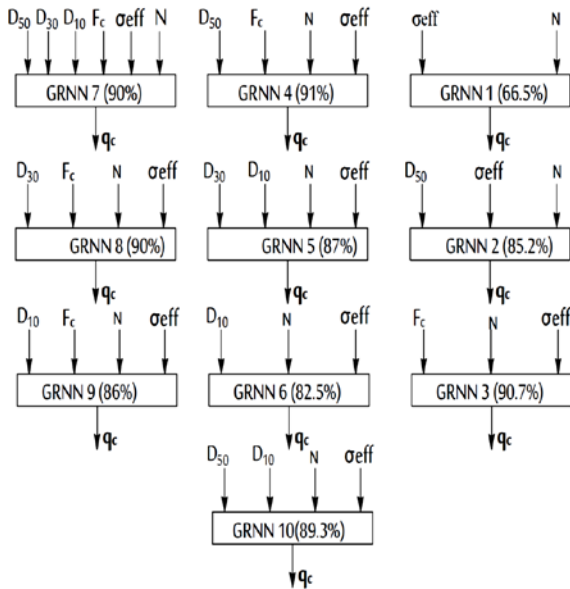

Fig. 8 Trials used to predict  $q_c$  from SPT results with  $r^2$  coefficient (%).

Fig. 9 The weight factors for the correlation between  $q_c$  (CPT result) and  $N$  (SPT result).

Fig. 10 Comparison between predicted and measured  $q_c$

for GRNN7.

### 6.3 Comparison between Neural Networks and a Set of Traditional Methods

Table 6 and Fig. 11 show some of the correlations used for estimation of  $q_c$  from SPT results available in the literature. It is clear from the figure that the ANN model yields better prediction of  $q_c$ .

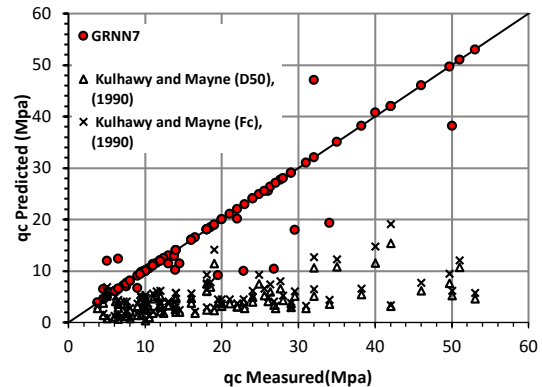

Fig. 11 Comparison between actual (measured) and predicted ( $q_c$ ) from SPT.

## 7. CONCLUSION

The paper studied the feasibility and efficiency of applying artificial neural networks (ANN) to predict  $\phi$  (angle of internal friction),  $E$  (modulus of elasticity) and  $q_c$  (CPT result) from SPT results ( $N$  values) which is one of the most commonly used in-situ tests. A large amount of data for cohesionless soil was used that was collected from a project covering most of UAE. The effect of different input parameters was investigated and ANN results were compared with other available correlations. The following can be concluded:

- The results of the ANN models developed for predicting  $\phi$ ,  $E$  and  $q_c$  from  $N$  gave a very good agreement with actual results compared to some of the traditional methods available in the literature.
- ANN model (GRNN2) with coefficient of correlation ( $r^2= 97.6\%$ ) and inputs ( $N$ ,  $\sigma_{eff}$ ) was the best model to represent the correlation of predicting ( $\tan\Phi$ ) from SPT results ( $N$ ) and effective overburden pressure ( $\sigma_{eff}$ ).
- ANN model (GRNN2) with  $r^2= 95.6\%$  and inputs ( $N$ ,  $D_{50}$ ) was the best model to represent the correlation of predicting ( $E$ ) from SPT results and grain size distribution.
- ANN model (GRNN7) with coefficient of correlation ( $r^2= 90\%$ ) and inputs ( $N$ ,  $\sigma_{eff}$ ,  $F_c$ ,  $D_{10}$ ,  $D_{30}$ , and  $D_{50}$ ) was the best model to represent the correlation of predicting ( $q_c$ ) from SPT results, effective overburden pressure and results of grain

size distribution tests.

Table 6 Different correlations for predicting (q<sub>c</sub>) from SPT results

Researcher	Correlation
Kulhawy and Mayne, (1990)	$(q_c/p_a)/N = 4.25 - \frac{F_c}{41.3}$
	$(q_c/p_a)/N = 5.44 D_{50}^{0.26}$
